# ECONOMIC BENEFITS OF AN EFFICIENT NORTH-SOUTH CORRIDOR 

Strategic Level Analysis of Investments in the North-South Corridor Using HDM-4

FINAL REPORT

## ACKNOWLEDGEMENTS

The authors are especially grateful to Eric Stannard and Andrew Otto for their substantial input in modelling the North-South corridor road network.

Many thanks go to John Patrick Donovan and Mark Pearson for initiating this study and providing guidance throughout the stages of the study. The Programme Management Unit of the Regional Trade Facilitation Programme and many others from the Road Agencies that manage the different road sections on the North-South Corridor have also made significant contributions in providing data for the study.

## EXECUTIVE SUMMARY

## Context

The primary aim of Aid for Trade is to assist developing countries to increase exports of goods and services, to integrate into the multilateral trading system, and to benefit from liberalised trade and increased market access.

The North-South Corridor is a pilot Aid for Trade programme which is being administered through the COMESA-EAC-SADC Tripartite process that focuses on transport and transit issues. The North-South Corridor runs between the port of Dar es Salaam in Tanzania to the Copperbelt of Zambia and DR Congo and down through Zimbabwe and Botswana to the ports in southern Africa, taking in 'spur' connections through Malawi and Mozambique in the east (See map in Figure 1.1). The pilot programme aims to bring together the initiatives which are taking place along this corridor and identify missing links and activities so that they can be dealt with in a coordinated manner.

The Project Management Unit (PMU) of RTFP (which provides the Secretariat to the COMESA-EAC-SADC task Team) is concerned to demonstrate that an efficient NorthSouth Corridor is economically viable to the region or otherwise. RTFP PMU therefore proposed to undertake a study with the main objective of preparing a global overarching economic document that would satisfy donors (and private funds) that ultimately an efficient North-South Corridor is economically viable in the medium to long term period. RTFP PMU commissioned the University of Birmingham (as Consultant) to use the Highway Development and Management (HDM-4) tool to conduct a strategic level study of the North-South Corridor to illustrate the primary economic benefits of an efficient North-South Corridor.

## Methodology

The methods used were based on a desk study of available data from the road agencies that manage the different sections within the North-South Corridor. The initial procedures of the study involved establishing a baseline case of the present situation within the corridor. This included a description of the various national economies and socioeconomic characteristics, a representation of the road infrastructure into homogeneous sections, definition of traffic characteristics in terms of volumes, loading and growth rates, and a representation of border posts and delays. The next step was to adapt and calibrate HDM-4 to local situation within the corridor, since the reliability of the results will
partly depend on this activity and partly on the input data. The set of data used for adaptation and calibration was obtained mostly from Malawi and Zambia.

The main data sets required as inputs for HDM-4 analyses were categorised under the road network, vehicle fleet, traffic, border post, and road works. The sources of data used in this study included RTFP GIS database www.rtfp.co.za; Road Agencies of Botswana, Malawi, Mozambique, Tanzania and Zambia; previous studies conducted in the region; and Internet literature review. Logical assumptions were made to fill in the gaps in cases where data were either lacking or missing. In summary 96 road sections of total length $10,547 \mathrm{~km}$ and 14 border posts were included in the study. A uniform traffic growth rate of 5 percent per annum was used. The border post crossings were modelled within the road network using dummy road sections with adjusted characteristics to simulate the delays experienced in real border crossing operations.

The study considered three road network improvement scenarios which were defined and compared against the base case scenario:

- Scenario RN-1: assumes that Road Agencies shall maintain the roads on the NorthSouth Corridor to an Excellent standard (i.e. technically at an average roughness of 2 IRI).
- Scenario RN-2: assumes that Road Agencies shall maintain the roads on the NorthSouth Corridor to a Very Good standard (i.e. technically at an average roughness of 3 IRI).
- Scenario RN-3: assumes that Road Agencies shall maintain the roads on the NorthSouth Corridor to a Good standard (i.e. technically at an average roughness of below 4 IRI).

The improvement scenarios involved widening the roads, where necessary, to a standard width of 7.3 metres and maintaining it by applying periodic maintenance and routine maintenance such that average long-term road condition will not exceed the specified threshold value.

An important aim of the study was to quantify benefits that may result from investments to reduce current delays at border posts along the North-South Corridor. To that end, three border post improvement scenarios were defined and compared against the base case scenario of maintaining the 'status quo':

- Scenario BP-1: considers that the current observed delays at border posts will be reduced by $10 \%$ after improvements
- Scenario BP-2: assumes that the current observed delays at border posts will be reduced by $20 \%$ after improvements
- Scenario BP-3: assumes that the current observed delays at border posts will be reduced by $50 \%$ after improvements are implemented

The border post improvement alternatives include investments specified to improve the infrastructure, management and operations at the border posts.

The study analysed various combinations of road section improvement and border post improvement scenarios. Two sets of analysis were carried out: one involved all the road sections on the North-South Corridor and the other excluded road sections in the Republic of South Africa.

## Summary Results

Different investment scenarios were analysed separately and the following are the main conclusions from the study:

- The most viable investment scenario in economic terms is for Road Agencies to maintain all the roads on the North-South Corridor in Good condition, which is denoted Scenario "RN-3, BP-3". Technically the long-term average road condition, over the 20 -year analysis period, would be 3.1 IRI. The total financial investment required for road network improvement is US\$ 9.1 billion of which US\$ 5.9 billion is capital investment and US\$ 3.2 billion is recurrent costs. The total financial requirement for border post improvement is US $\$ 0.73$ billion of which US $\$ 0.26$ billion is capital investment and US $\$ 0.47$ billion is recurrent costs. The annualised financial requirement to improve the road network is approximately US\$ 43,100 per km. The economic return on this investment (i.e. the NPV) would be US\$ 29.2 billion. The benefit/capital cost ratio associated with this investment is 6.5 .
- When road sections from the Republic of South Africa are excluded from the analysis, investment scenario "RN-3, BP-3" still remains the most economically attractive. The long-term average road condition, over the 20 -year analysis period, would be 3.6 IRI. The total financial investment required for road network improvement is US\$ 6.9 billion of which US\$ 4.5 billion is capital investment and US\$
2.4 billion is recurrent costs. The total financial requirement for border post improvement is US $\$ 0.73$ billion of which US\$ 0.26 billion is capital investment and US\$ 0.47 billion is recurrent costs. The annualised financial requirement to improve the road network is approximately US $\$ 40,000$ per km . The economic return on this investment (i.e. the NPV) would be US\$ 13.9 billion. The benefit/capital cost ratio associated with this investment is 3.1 .
- The results of sensitivity analysis have indicated that even at zero percent rate of traffic growth (to crudely assess the effect of traffic diversion to other transport modes and routes/corridors) the NPV of investment scenario "RN-3, BP-3" is still positive US\$ 15.1 billion for all road sections, and positive US $\$ 7.6$ billion when road sections in the Republic of South Africa are excluded.
- The results show that in the initial years of the 20-year analysis period, higher amounts of investment expenditures are required to eliminate maintenance backlogs and raise the road standard to an appropriate level for the North-South Corridor.
- The approximate timing when the cumulative net economic benefit of investments will become positive was determined to be Year 9 (with RSA roads included) and Year 7 (without RSA roads) for investment scenario RN-2 (i.e. the Road Agencies shall maintain the roads on the North-South Corridor to Very Good condition); and Year 7 (with RSA roads) and Year 5 (without RSA roads) for Scenario RN-3. It is important to note that this does not imply that the inclusion of road sections in RSA makes the investment cases economically less attractive. On the contrary, analysis results have shown that the benefit/ capital cost ratios are higher when road sections in RSA are included. This perhaps stresses the need for carrying out a financial analysis of the corridor roads, the results of which would indicate to the private sector when they could get seriously involved in investing in the North-South Corridor.
- The NPV of selected key routes within the North-South corridor have also been determined to show the degree of economic attractiveness of each route. A full road works programme for 20 years has also been produced showing when each section is to receive an intervention with costs.

This study has demonstrated that there is an attractive rate of return to be realised from investment in the North-South Corridor. The study was based on an appropriate methodology and a more advanced use of the highway development and management (HDM-4) tool.

## The Way Forward

It should be noted that the reliability of the results of any studies using prediction models such as HDM-4 is dependent upon two primary considerations:

- How well the data provided to the model represent the reality of the current conditions and influencing factors, in the terms understood by the model; and,
- How well the predictions of the model fit the real behaviour and the interactions between various factors for the conditions prevailing in the countries and regions to which it is applied.

Although the study team made great effort to obtain reliable input data and calibrate the models, available project resources limited these tasks. Nevertheless, the rigorous sensitivity analysis conducted has confirmed the robustness of the results obtained. Largely, default HDM-4 model parameters and data obtained from desk studies were used. Confidence in using the results obtained from this study could be increased through additional studies to:

1. Calibrate HDM-4 models to conditions within the North-South Corridor to Level 2 Calibration;
2. Validate the data held by the various road agencies that manage road sections within the corridor in order to determine their appropriateness for use in future studies of the North-South Corridor;
3. Investigate the impact of overloading of goods vehicles on road deterioration; and
4. Carry out a financial analysis of investments in the North-South Corridor to assess how the private sector could get involved, for example, through Public-Private-Partnership (PPP) or other appropriate investment models.

## 1 INTRODUCTION

### 1.1 Background

Developing countries devote a considerable proportion of total infrastructure investment to roads and yet recent research suggests that isolation from regional and international markets has contributed significantly to poverty in many SubSaharan African countries. The international community has responded to this situation by calling for an increase in Aid for Trade in terms of resource quantities and efficiency in their utilisation. The primary aim of Aid for Trade is to assist developing countries to increase exports of goods and services, to integrate into the multilateral trading system, and to benefit from liberalised trade and increased market access.

The Regional Economic Communities (REC) of the Common Market for Eastern and Southern Africa (COMESA), the Southern Africa Development Community (SADC) and the East African Community (EAC) have long recognised the importance of improving trade facilitation in the context of deepening regional integration and in reducing the costs of cross-border transactions and so improving livelihoods. As such, the RECs have supported a number of trade facilitation instruments as well as developing plans for regional infrastructural development programmes, www.rtfp.org (October 2008).

The North-South Corridor runs between the port of Dar es Salaam in Tanzania to the Copperbelt of Zambia and Democratic Republic of Congo and down through Zimbabwe and Botswana to the ports in southern Africa, taking in 'spur' connections to Malawi and Mozambique in the east (See map in Figure 1.1). The pilot programme aims to bring together the initiatives which are taking place along this corridor and identify missing links and activities so that they can be dealt with in a coordinated manner.

The Project Management Unit (PMU) of RTFP is concerned to demonstrate that an efficient North-South Corridor is economically viable to the region or otherwise. RTFP PMU therefore proposed to undertake a study with the main objective of preparing a global overarching economic document that would satisfy donors (and private funds) that ultimately an efficient North-South Corridor is economically viable in the medium to long term period. RTFP PMU
commissioned the University of Birmingham (as Consultant) to use the Highway Development and Management (HDM-4) tool to conduct a strategic level study of the North-South Corridor to illustrate the primary economic benefits of an efficient North-South Corridor.

This document describes the methodology and procedures used to conduct the first stage of the study and the results obtained.

Figure 1.1: Map of the North-South Corridor

### 1.2 Project Aim and Objectives

The main aim of the first stage of the study is to prove the feasibility of using HDM-4 to show, at the strategic level, the economic benefits of an efficient NorthSouth Corridor in relationship to trade in the region.

The specific objectives are as follows:

- To prepare and apply HDM-4 at a strategic level to study the impact of different road investment alternatives on the North-South Corridor road network
- To determine the need for a further study of the North-South Corridor.

### 1.3 Scope of the Project

In order to achieve the objectives of this project, the Consultant carried out a number of tasks which are summarised as follows:

- Established a baseline case of the present economic situations within the Corridor
- Defined the link characteristics within the corridor and the network structure for HDM-4 application
- Identified, collected and processed data needed for the specific study including the present vehicle characteristics as well as expected new vehicle types that will use the corridor once it is improved.
- Adapted HDM-4 to local conditions, initially achieved a Level 1 Calibration of HDM-4 models
- Developed several investment scenarios for the North-South Corridor which took into account growth in trade, traffic and the economy.
- Specified different road improvement alternatives for the corridor and for each future scenario that was analyzed
- Carried out a number of HDM-4 runs as were necessary for all the combinations of factors and improvement alternatives, and conducted analyses of the results
- Documented the study methodology, procedures and results

### 1.4 Project Deliverables

The main project deliverables include the following:

- A customized HDM-4 Workspace for North-South Corridor
- Strategic level studies related to agreed future road network improvement scenarios and their financial, economic and technical impacts
- Project final report

## 2 STUDY METHODOLOGY

### 2.1 Present situation within the North-South Corridor

## Economy

The economy in the region serviced by the North-South Corridor can be summarily indicated by the level and growth rates of the following parameters: gross domestic products (GDP), population, and traffic. Table 2.1 gives the GDP and population figures for the countries in the region and compares these with the totals for Sub-Saharan Africa.

Table 2.1: GDP and Population as Economic Indicators

| Country | GDP <br> (Billion US\$) | GDP Growth (\%) | Population (Millions) | Population Growth (\%) |
| :---: | :---: | :---: | :---: | :---: |
| Botswana | 12.0 | 4 | 2 | 1.2 |
| Democratic Republic of Congo | 9.0 | 6 | 62 | 3.0 |
| Malawi | 3.6 | 7 | 14 | 2.5 |
| Mozambique | 7.8 | 7 | 21 | 2.0 |
| Republic of South Africa | 278.0 | 5 | 48 | 0.4 |
| Tanzania | 16.0 | 7 | 40 | 2.4 |
| Zambia | 11.0 | 6 | 12 | 2.0 |
| Zimbabwe* | 3.4 | -5 | 13 | 1.3 |
| N-S Corridor Estimate | 340.8 | 5 | 212 | 1.9 |
| Sub-Saharan Africa | 843.0 | 6 | 800 | 2.4 |

Source: World Bank (2007)
Note: * Figures for 2005

The North-South Corridor is the busiest in the region in terms of values and volumes of freight. The road network is already under pressure in relation to its design capacities and in terms of delays at strategic points, such as border posts. A number of mineral deposits within the region have become economically interesting and increased levels of mining activities will lead to increased volumes of exports and imports with consequential heavy loading of the North-South road infrastructure.

## Road infrastructure

The road network comprises mainly paved roads of asphalt concrete and surface treatment. It is generally in fairly good condition although there are sections of road that are in urgent need of rehabilitation and improvement. There are also heavily trafficked sections that may create bottlenecks in terms of structural capacity, and cause closure of the whole network if blocked e.g. bridge crossings.

Table 2.2 gives a summarised distribution of the road sections included in this study. Details of the road sections are provided in Appendix A.

Table 2.2: Summary of Road Sections in the North-South Corridor

| Country | Number of <br> Sections | Length <br> (in km) | Network <br> Coverage (\%) |
| :--- | :---: | :---: | :---: |
| Botswana | 6 | 1,037 | 10 |
| DR Congo | 4 | 400 | 4 |
| Malawi | 14 | 1,128 | 11 |
| Mozambique | 4 | 263 | 2 |
| Republic of South Africa | 8 | 1,901 | 18 |
| Tanzania | 9 | 1,013 | 10 |
| Zambia | 38 | 2,638 | 25 |
| Zimbabwe | 13 | 2,169 | 21 |
| Total | $\mathbf{9 6}$ | $\mathbf{1 0 , 5 4 7}$ | $\mathbf{1 0 0}$ |

## Traffic characteristics

Current traffic on the North-South Corridor is characterised by exports of mining and agricultural products and imports of manufactured goods. The main operating feature of the regional road transport routes identified by RTFP (2008), which affects transport efficiency, costs and tariffs, is the severe imbalance of freight flows, leading to empty return hauls. This imbalance can be seasonal and an empty return haul by road effectively means that the transport cost almost doubles. The current traffic data collected as part of the study are given in Section 2.3. Table 2.3 gives a summary of the average daily vehicle-kilometres by country. This shows that the roads in the Republic of South Africa carry over $69 \%$ of the total number of vehicle-kilometres in North-South Corridor. The number of medium and heavy goods vehicles, expressed as a percentage of the
total vehicle-kilometres for each country, varies from about 21.9\% in Botswana to 45.3\% in DR Congo.

Table 2.3: Average Daily Vehicle-Kilometres in the North-South Corridor

| Country | Average Daily <br> Veh-km | Percent of <br> Average Daily <br> Veh-km | Percent of country Veh- <br> km by Medium and <br> Heavy Goods |
| :--- | ---: | :---: | :---: |
| Botswana | $2,187,283$ | 4.4 | 21.9 |
| DR Congo | 167,821 | 0.3 | 45.3 |
| Malawi | $4,671,092$ | 3.4 | 26.5 |
| Mozambique | $34,370,000$ | 69.1 | 25.9 |
| Republic of South <br> Africa | $2,711,333$ | 5.5 | 25.8 |
| Tanzania | $3,993,962$ | 8.0 | 30.7 |
| Zambia | $4,223,500$ | 8.5 | 26.8 |
| Zimbabwe |  | 25.9 |  |

Overloading on the Corridor is an issue based on specific studies in the region. Regional freight traffic is usually carried in large double trailer, seven-axle combination rigs, with a maximum gross vehicle mass (GVM) of 56 tonnes. In order to preserve the road infrastructure and ensure reasonable usable life times, countries in the region have generally agreed the following axle load limits (RTFP, 2008): single-steering-axle two tyres 8 tonnes, single-axle dual-tyres 10 tonnes, tandem axle four tyres 16 tonnes, tandem axle dual tyres 18 tonnes, triple axle six tyres 24 tonnes, and triple axle twelve tyres 24 tonnes. However, not all countries apply these axle loading limits. According to one report ANE (2007) of a study on axle load survey in Mozambique, it was found that $35 \%$ of trucks were overloaded by $34 \%$.

In this study, the impacts of overloading on the Corridor were reflected in the models in terms of increased road deterioration and agency costs resulting from higher equivalent standard axle loads, and increased vehicle operation costs as a consequence of higher GVM.

## Border posts and delays

It has been estimated that the cost of current delays at border post crossings in the region amount to many millions of US dollars. Table 2.4 presents the Border Posts in the North-South Corridor. Typical values of border delays at Chirundu Border Post are given in Section 2.3.

Table 2.4: Border Posts in the North-South Corridor

| No | Name of Post | Countries Joined |
| :---: | :--- | :--- |
| 1 | Kasumbalesa | DR Congo - Zambia |
| 2 | Tunduma BP | Tanzania - Zambia |
| 3 | Songwe | Tanzania - Malawi |
| 4 | Victoria Falls | Zambia - Zimbabwe |

| 13 | Martin's Drift | Republic of South Africa - Botswana |
| 14 | Nyamapanda | Zimbabwe - Mozambique |

### 2.2 HDM-4 as the Analytical Tool

HDM-4 was used as the analytical tool for this project. The HDM-4 analytical framework (Odoki and Kerali, 2000) is based on the concept of pavement life cycle analysis, which is typically 15 to 40 years. This is applied to predict road deterioration, road works effects, road user effects and socio-economic and environmental effects.

After its construction, a road pavement deteriorates as a consequence of several factors, most notably: traffic volume and loading, pavement design, material types, construction quality, environmental weathering and the effect of inadequate drainage systems. The rate of pavement deterioration is directly
affected by the standards of maintenance applied to repair defects on the pavement surface or to preserve the structural integrity of the pavement thereby permitting the road to carry traffic in accordance with its design function. Consequently, in addition to the capital costs of road construction, the total costs that are incurred by road agencies will depend on the standards of maintenance and improvement applied.

The impacts of the road condition (as well the road design standards) on road users are measured in terms of road user costs (RUC), and other social and environmental effects. RUC comprise: vehicle operation costs (i.e., fuel, tyres, depreciation, etc.), costs of travel time for both passengers and cargo due to road condition and traffic congestion, and costs to the economy of road accidents (i.e., loss of life, injury to road users, damage to vehicles and roadside objects). The social and environmental effects comprise: vehicle emissions, energy consumption, traffic noise and other welfare benefits to the population served by the roads.

The interacting sets of costs, related to those incurred by the road authority and those incurred by the road users, are added together over time in discounted present values. Economic benefits are then determined by comparing the total cost streams for various maintenance and construction alternatives with a base case, typically a 'do nothing' or minimum maintenance scenario. For this research, economic benefits were calculated as the difference between the do minimum option and the various scenarios for both options. The HDM-4 model was used to simulate future changes to the North-South Corridor road system from current conditions. The reliability of the results is dependent upon two primary considerations (Bennett and Paterson, 2000):

1. How well the data provided to the model represent the reality of current conditions and influencing factors, in the terms understood by the model; and,
2. How well the predictions of the model fit the real behaviour and the interactions between various factors for the variety of conditions to which it is applied.

Application of the HDM-4 model thus involves two important initial steps:

1. Data input: a correct interpretation of the data input requirements, and achieving a quality of input data that is appropriate to the desired reliability of the results.
2. Calibration of output: adjusting the model parameters to enhance the convergence of the computed road behaviour with that observed in the field for the various interventions. Calibration of the HDM model focuses on the components that determine the physical quantities, costs and benefits predicted by the analyses.

Since HDM-4 is designed to be used in a wide range of environments, it needed to be configured to reflect the North-South Corridor characteristics. The data for this relates to traffic flows, climate zones and road types. Calibration is intended to improve the accuracy of predicted pavement performance and vehicle resource consumption. A fundamental assumption made prior to using HDM-4 is that the pavement performance models will be calibrated to reflect the observed rates of pavement deterioration on the roads where the models are applied. The extent of calibration may be defined as follows:

Level 1: Application: based on a desk study of available data and engineering experience of pavement performance.

Level 2: Verification: based on measured pavement condition data collected from a large number of road sections.

Level 3: Adaptation: experimental data collection required to monitor the longterm performance of pavements within the study area.

This study used Level 1 calibration, where the focus was on calibrating the key road deterioration models for cracking, rutting, and roughness-age-environmental effects; and road user effects models for vehicle speeds. The calibration data used were obtained from Malawi and Zambia. For strategic level analysis this together with HDM-4 default data was considered adequate although it would have been most useful to obtain information from the other countries.

### 2.3 Data Requirements

## Overview

The main data sets required as inputs for HDM-4 analyses are categorised as follows:

1. Road network data: include inventory, geometry, pavement type, pavement strength, road condition
2. Vehicle fleet data: include vehicle physical characteristics, tyres, utilisation, loading and performance.
3. Traffic data: include details of traffic composition, volumes and growth rates, speed-flow types and traffic flow pattern.
4. Border post data: include delays and associated costs.
5. Road works data: include a range of construction and maintenance work items together with their unit costs.

The sources of data used in this study included the following:

- RTFP GIS database www.rtfp.co.za
- Road Agencies of Malawi, Zambia, Tanzania, Mozambique, Botswana, the Republic of South Africa and Botswana
- Previous studies conducted in the region
- Internet literature review
- HDM-4 parameter default values

## Road network data

The road network structure adopted in this study is based on the RTFP GIS database for the North-South Corridor www.rtfp.co.za. The roads in the NorthSouth Corridor were defined as a series of homogeneous road sections with unique characteristics.

The Study Team defined the key data items required for HDM-4 analysis in a set of tables and sent these out to the Road Agencies of the interested countries. Some road agencies completed the tables with particular attention while others
were not able to return their data in the format required. The list of sections studied and the key data required are given Table A. 1 in Appendix A. The map given in Figure 1.1 shows the North-South Corridor road network. The climatic data used is given in Table A. 2 in Appendix A. A major assumption made in this study was that the data provided by the different road agencies and those obtained from the RTFP GIS database were reasonably accurate for strategic network level analysis. The overall confidence level in the project data used have been qualitatively assessed and categorised by the Study Team as given in Table 2.5.

Table 2.5: Overall Confidence Level in the Data Used in this Study

| Data by Country | Network Coverage (\%) | Qualitative Confidence <br> Level |
| :--- | :---: | :---: |
| Botswana | 10 | Low-Medium |
| DR Congo | 4 | Low |
| Malawi | 11 | Medium-High |
| Mozambique | 2 | Medium |
| Republic of South Africa | 18 | Medium-High |
| Tanzania | 10 | Medium |
| Zambia | 25 | Medium-High |
| Zimbabwe | 21 | Low-Medium |

## Vehicle fleet data

A representation of the vehicle fleet that use the North-South Corridor was based on grouping vehicles of similar characteristics and the types of goods they carry. This resulted in the following six vehicle categories:
(i) Cars and Utilities including Four-wheel Drives and Pick-up
(ii) Light Goods Vehicles
(iii) Mini-bus
(iv) Bus
(v) Medium Goods Vehicles
(vi) Heavy Goods Vehicles

The key vehicle fleet data used in this study were obtained from the Road Agencies and these are presented in Table B. 1 given in Appendix B. HDM-4 default data were used were local data were not available.

## Traffic data

The traffic data used in this study include annual average daily traffic (AADT) and composition by vehicle types for each road section, and average traffic growth rate. The AADT data were mainly obtained from the Road Agencies except for road sections in Zimbabwe and the Democratic Republic of Congo for which the AADT values were estimated.

The AADT for the road sections in Zimbabwe and the Democratic Republic of Congo were estimated by first considering the traffic through the border posts with Zambia crossing into the respective countries. The partial AADT estimates of through borders traffic were then adjusted to full section AADT values by considering factors such as road class, junctions and socio-economic characteristics of the respective countries.

Details of two-way AADT including traffic composition for each of the sections studied are given in Table C. 1 in Appendix C. In cases where two or more traffic sections were represented by a single road section in the study, a weighted average AADT value (based on section lengths) was used. The traffic data shows that 28 percent of the traffic comprises medium and heavy goods vehicles.

The main factor driving traffic growth on the North-South Corridor is trade and associated movement of goods. It is envisaged that passenger travels will also increase significantly in the years to come. A single annual traffic growth rate of 5 percent was assumed for the entire North-South Corridor although the GDP growth rate in the region would indicate a higher traffic growth rate based on the conceptual relationship that traffic growth rate approximates to $1.5^{*}$ GDP. However, the use of 5 percent value is supported by several studies conducted on parts of the Corridor including one in Zambia and that by Nippon Koei and Oriental Consultants for SADC in 2007. In order to account for the effects of possible variation in traffic growth rate, sensitivity tests were carried out and this is reported under Section 3.7.

## Modelling delays at border posts

The modelling of delays at border posts necessitated advanced (or special) use of HDM-4 in order to study the related impacts. The border post crossings were modelled within the road network using dummy road sections with adjusted characteristics to simulate the delays experienced in real border crossing operations. Figure 2.1 illustrates the representation of the dummy links and the traffic characteristics associated with each dummy link labelled $A, B$ and $C$.

Figure 2.1: Border Post Crossing Model
The vehicles using link A are Passenger Cars, Buses, Mini-Buses, Light vehicles; the vehicles using link B are Refrigerated Trucks, Oil Tankers; and the vehicles using link $C$ are Heavy Trucks, Containerised. The AADT for each dummy link was determined on the basis of the traffic composition on the border approach road sections.

As an example of the modelling approach described above, the details of border post delays at Chirundu are presented in Table 2.6.

Table 2.6: Border Post Delays at Chirundu

| Dummy <br> Link | Vehicles types | Travel Direction | Delays <br> (in Hrs) |
| :---: | :--- | :---: | :---: |
|  | Passenger Cars, Buses, Mini- <br> Buses, Light vehicles | North-bound | 1 |
|  | B | Refrigerated Trucks, Oil Tankers | South-bound |
|  |  | North-bound | 28.5 |
| C | Heavy Trucks, Containerised | North-bound | 7 |
|  |  | South-bound | 40.5 |

Source: Transport Logistic Consultants

In modelling using HDM-4, the total cost of delays at border posts is calculated from the sum of the following cost components: value of goods delayed, additional vehicle crew cost, additional overhead cost, and passenger time value.

## Road works and unit costs

The primary sources of the unit cost data were World Bank ROCKS and Road Agencies within the N-S Corridor. Tables 2.7 and 2.8 show the assumed border post investments and maintenance costs and a summary of the unit costs used for road works.

Table 2.7: Border Post Investment and Maintenance Costs

| Border Post | Investment <br> (Million US\$) | Maintenance Cost/Year <br> (Million US\$) |
| :--- | :---: | :---: |
| Kazangula | 100 | 1 |
| Beit Bridge | 50 | 1 |
| Kasembulesa | 20 | 1 |
| Others | 10 | 1 |

## Table 2.8: Road Works and Unit Costs

| Work Type | Description | Economic <br> Costs <br> (US $\$$ ) | Financial <br> Costs <br> (US\$) | Units |
| :--- | :--- | :---: | :---: | :---: |
| Patching Potholes | Repair of surface distresses such as potholing, wide structural cracking and ravelling | 34 | 40 | $\mathrm{~m}^{2}$ |
| Edge Break Repair | Patching edge failures on paved roads | 42.6 | 50 | $\mathrm{~m}^{2}$ |
| Crack Sealing | Treatment of transverse thermal cracking and wide structural cracking on paved <br> roads | 17 | 20 | $\mathrm{~m}^{2}$ |
| Miscellaneous Works | Includes shoulder repairs, vegetation control, road sign repairs and replacement, line <br> marking, guardrail repair and replacement, etc. | 2,125 | 2,500 | Per km per <br> Year |
| Regravelling | Regravelling existing unpaved road to a final grave thickness of 150mm | 109 | 133 | $\mathrm{~m}^{2}$ |
| Heavy Grading | Heavy motorised grading of unpaved roads with water and light roller compaction | 595 | 700 | $\mathrm{~m}^{2}$ |
| Spot Regravelling | Spot regravelling to unpaved roads to replace 80\% of annual material loss | 123 | 150 | $\mathrm{~m}^{2}$ |
| Cape seal | Cape seal with shape correction | 12.75 | 15 | $\mathrm{~m}^{2}$ |
| Surface Dressing | Single sealing of the carriageway with shape correction in order to delay major <br> intervention and to renew the skid resistance. | 5.95 | 7 | $\mathrm{~m}^{2}$ |
| 50 mm Overlay | 50mm overlay to existing asphalt concrete road. | 21.25 | 25 | $\mathrm{~m}^{2}$ |
| 80mm Overlay | 80mm Overlay to existing asphalt concrete road. | 34 | 40 | $\mathrm{~m}^{2}$ |
| Reconstruction (STGB) ${ }^{1}$ | Reconstruction of existing surface treatment road comprising double surface dressing <br> on granular base | 59.5 | 70 | $\mathrm{~m}^{2}$ |
| Reconstruction (AMGB) $)^{2}$ | Pavement reconstruction of existing asphalt concrete road comprising 50mm asphalt <br> concrete surfacing on granular base. | 85 | 100 | $\mathrm{~m}^{2}$ |
| Partial Widening (STGB) ${ }^{1}$ | Widening of existing asphalt mix roads to 7.3 m width where necessary and providing <br> a 50mm overlay to existing surfacing | 85,000 | 100,000 | Per Km |
| Partial Widening (AMGB) $)^{2}$ | Widening of existing asphalt mix roads to $7.3 m$ width where necessary and providing <br> a 50mm overlay to existing surfacing | 127,500 | 150,000 | Per Km |
| Upgrade gravel road | Upgrading existing gravel road to a 7.3m wide asphalt mix on granular base road | 680,000 | 800,000 | Per Km |

[^0]
### 2.4 Economic Analysis Components and Parameters

## Road network improvement scenarios

The study considered three road network improvement scenarios which were defined and compared against the base case scenario. Table 2.9 gives the definition of these scenarios.

Table 2.9: Road Network Scenarios

| Scenario | Target Condition |
| :--- | :--- |
| Base Case Scenario | Comprises routine maintenance works and activities |
| Scenario RN-1 | This scenario assumes that the Road Agencies shall <br> maintain the roads on the North - South Corridor in <br> Excellent condition in the long-term. |
| Scenario RN-2 | This scenario assumes that the Road Agencies shall <br> maintain the roads on the North - South Corridor in Very <br> Good condition in the long-term. |
| Scenario RN-3 | This scenario assumes that the Road Agencies shall <br> maintain the roads on the North - South Corridor in Good <br> condition in the long-term. |

For each scenario, two investment alternatives were defined as follows:

1. "Do minimum" alternative: aimed at preserving the existing asset using recurrent expenditure for routine maintenance.
2. Improvement alternative: aimed at improving the road standard and maintaining it by applying periodic maintenance and routine maintenance such that average long-term road condition will not exceed a certain threshold roughness value.

For each alternative, road work standards were defined in such a way that the objective of the scenario can be achieved. A work standard comprises one or more works item (e.g., overlay, reseal, patching), defined intervention criteria to determine the timing, design characteristics, the unit costs, and the after works effects. The unit costs of works items are given in Table 2.8. Tables 2.10 to 2.13 present the work standards defined for each road network improvement scenarios.

Table 2.10: Base Case Scenario Standard

| Work Types | Intervention Criteria |  |  |  | After Works Effects |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Patching Potholes | Potholing | >= | 10 no./km |  | Repair to $100 \%$ of potholes, TLF $^{1}=2$ months. |
| Edge Break Repair | Edge break | >= | $5 \mathrm{~m}^{2} / \mathrm{km}$ |  | Repair to $100 \%$ of edge breaks |
| Crack Sealing | Wide Structural Cracking |  |  |  | Repair to $100 \%$ of thermal cracks, and wide structural cracks |
| Miscellaneous Works | Interval | >= | 1 Year |  | N/A |
| Regravelling | Gravel <br> Thickness | <= | $150 \text { mm }$ |  | Roughness >= 3.0 IRI |
|  | Roughness | >= | 5 IRI | AND |  |
|  | Interval | >= | 90 days |  |  |
| Spot Regravelling | Interval | >= | 1 Year |  |  |

Notes:

1. TLF $=$ Time Lapse Factor
2. Work types are described in Table 2.8

Table 2.11: Scenario RN-1 Standard

| Work Types | Intervention Criteria |  |  | After Works Effects |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Routine maintenance <br> Includes: potholes, edge breaks, carriageway cracks, spot regravelling, and heavy grading | To be performed every year |  |  | Determined using HDM-4 relationships |  |  |
| 80 mm Overlay | Roughness | >= | 2 IRI | Roughness |  | 1.8 IRI |
| 50 mm Overlay | Roughness | >= | 2 IRI | Roughness | $=$ | 1.8 IRI |
| Reconstruction Asphalt Mix | Roughness |  | 7 IRI | Roughness | $=$ | 1.2 IRI |
| Reconstruction Surface Treatment on Granular Base | Roughness | >= | 7 IRI | Roughness | $=$ | 1.2 IRI |
| Cape seal | Roughness | >= | 2 IRI | Roughness | $=$ | 2.0 IRI |
| Surface dressing | Roughness | >= | 2 IRI | Roughness | $=$ | 2.0 IRI |
| Partial Widening Asphalt Mix | AADT |  | 5000 Veh/day | Roughness | $=$ | 1.5 IRI |
| Partial Widening Surface Treatment | AADT |  | 4000 <br> Veh/day | Roughness | $=$ | 1.5 IRI |
| Upgrade gravel road | AADT |  | 500 Veh/day | Roughness | $=$ | 1.5 IRI |

Notes

1. Work types are described in Table 2.8

Table 2.12: Scenario RN-2 Standard

| Work Types | Intervention Criteria |  | After Works Effects |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Routine maintenance <br> Includes: potholes, edge breaks, carriageway cracks, spot regravelling, and heavy grading | To be performed every year |  | Determined using HDM-4 relationships |  |  |
| 80 mm Overlay | Roughness | >= 3 IRI | Roughness |  | 2.5 IRI |
| 50 mm Overlay | Roughness | >= 3 IRI | Roughness | = | 2.5 IRI |
| Reconstruction Asphalt Mix | Roughness | >= 7 IRI | Roughness |  | 2.0 IRI |
| Reconstruction Surface Treatment on Granular Base | Roughness | >= 7 IRI | Roughness |  | 2.2 IRI |
| Cape seal | Roughness | >= 3 IRI | Roughness |  | 2.8 IRI |
| Surface dressing | Roughness | >= 3 IRI | Roughness | $=$ | 2.9 IRI |
| Partial Widening Asphalt Mix | AADT | $\begin{array}{ll}  & 5000 \\ >= & \text { Veh/day } \end{array}$ | Roughness |  | 1.5 IRI |
| Partial Widening Surface Treatment | AADT | $\begin{array}{ll}  & 4000 \\ >= & \text { Veh/day } \end{array}$ | Roughness |  | 1.5 IRI |
| Upgrade gravel road | AADT | $\begin{array}{ll}  & 500 \\ >= & \text { Veh/day } \end{array}$ | Roughness |  | 1.5 IRI |

Notes

1. Work types are described in Table 2.8

Table 2.13: Scenario RN-3 Standard

| Work Types | Intervention Criteria |  | After Works Effects |
| :--- | :--- | :--- | :--- |
| Routine maintenance <br> Includes: potholes, <br> edge breaks, <br> carriageway cracks, <br> spot regravelling, and <br> heavy grading | To be performed every year | Determined using HDM-4 <br> relationships |  |
| 80 mm Overlay | Roughness >= 4 IRI | Roughness = 2.5 IRI |  |
| 50 mm Overlay | Roughness $>=4$ IRI | Roughness $=2.5$ IRI |  |
| Reconstruction <br> Asphalt Mix | Roughness $>=7$ IRI | Roughness $=2.0$ IRI |  |
| Reconstruction <br> Surface Treatment on <br> Granular Base | Roughness $>=7$ IRI | Roughness $=2.2$ IRI |  |
| Cape seal | Roughness $>=4$ IRI | Roughness $=2.8$ IRI |  |
| Surface dressing | Roughness $>=4$ IRI | Roughness $=2.9$ IRI |  |
| Partial Widening <br> Asphalt Mix | AADT | $>=5000$ | Roughness $=1.5$ IRI |
| Partial Widening <br> Surface Treatment | AADT | $>=4000$ | Roughness $=1.5$ IRI |
| Upgrade gravel road | AADT | $>=500$ Veh/day | Roughness $=1.5$ IRI |

Notes

1. Work types are described in Table 2.8

## Border post improvement scenarios

An important aim of the study was to quantify benefits that may result from investments to reduce current delays at border posts along the North-South Corridor. To that end, three border post improvement scenarios were defined and compared against the base case scenario of maintaining the 'status quo'. Table 2.14 gives the definition of these border post scenarios.

Table 2.14 Border Post Scenarios

| Scenario | Target Condition |
| :--- | :--- |
| Base Case Scenario | Comprises annual lump sum costs for maintaining each <br> border crossing without improvement to the prevailing delays |
| Scenario BP-1 | Considers that current observed delays at border posts shall <br> be reduced by10\% of observed delays |
| Scenario BP-2 | Assumes that current observed delays at border posts shall <br> be reduced by 20\% once improvements to border crossings <br> are implemented |
| Scenario BP-3 | Assumes that current observed delays at border posts shall <br> be reduced to 50\% once improvements to border crossings <br> are implemented |

For each scenario, the base alternative defined assumes that an annual lump sum amount of US\$ 1 million will be used to maintain and operate each border post. The consequence of this is that delays at the border posts will not reduce; in fact it should most likely increase if traffic volume increases.

The border post improvement alternatives include investments specified to improve the infrastructure, management and operations at the border posts, the timing of the improvement works, and the effects of the improvement works in terms of reduction in delays at border crossings. It was assumed that once improvement works are implemented, an annual lump sum cost of US\$ 1 million will be necessary to cover annual maintenance and operation needs at each border crossing. Table 2.15 gives the border post improvement alternatives used in the study.

Table 2.15: Border Post Investments

| Border <br> Crossing | Investment <br> Year $^{1}$ | Investment (US\$ Millions) |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathbf{0 \%}$ <br> Reduction <br> in Delays | $\mathbf{1 0 \%}$ <br> Reduction <br> in Delays | $\mathbf{2 0 \%}$ <br> Reduction <br> in Delays | $\mathbf{5 0 \%}$ <br> Reduction <br> in Delays |
| Kazangula | $6^{\text {th }}$ | 0 | 100 | 100 | 100 |
| Beit Bridge | $6^{\text {th }}$ | 0 | 50 | 50 | 50 |
| Kasembulesa | $6^{\text {th }}$ | 0 | 20 | 20 | 20 |
| Others | $6^{\text {th }}$ | 0 | 10 | 10 | 10 |

Notes

1. Investment year means the $\mathrm{n}^{\text {th }}$ year from the start of the analysis period.

Since it is not known exactly what the reduction in delays would be following a given level of investment, it was necessary to test the assumptions that the same investment levels may yield different reduction amounts of delays, which have been specified as $50 \%, 20 \%$ and $10 \%$ of the current level of delays at each border post.

## 3 ANALYSIS RESULTS

### 3.1 General

Two sets of analysis were undertaken. The first set considered all the road sections within the North-South Corridor while the second set excluded road sections within the Republic of South Africa (RSA). The results of the analysis for the two sets are reported as "with RSA roads" and "without RSA roads".

The road network improvement scenarios defined in Section 2.4, were combined logically with the border post improvement scenarios to form different investment scenarios. For example, road network improvement scenario RN-3 was combined with border post improvement scenario BP-3 to form investment scenario "RN-3, BP-3" which was then analysed separately. The analysis results are presented under the following categories:

- Road condition trend: showing annual predictions of pavement performance
- Investment Needs: showing annual and total financial requirements, types and timing of works
- Economic Benefits: providing economic indicators e.g. Net Present Values
- Cumulative Net Benefits: showing the time when cumulative net economic benefits becomes positive
- Net Present Value of Routes: showing the attractiveness of investing in particular routes
- Sensitivity Analysis: investigating the impact of variations in key parameter on the analysis results

### 3.2 Road Condition Trends

The predicted average road network condition trends for the Base Case Scenario and Scenarios RN-1 (Excellent), RN-2 (Very Good) and RN-3 (Good) are shown in Figure 3.1 (without RSA roads) and Figure 3.2 (with RSA roads). The initial average roughness of about 5 IRI without RSA road sections and 4.3 IRI with RSA road sections confirms the effect of good road condition in the Republic of South Africa. The predicted average roughness values over the 20 year analysis period for these scenarios are given in Table 3.1.

Table 3.1: Predicted Average Road Condition Over 20 Years

| Scenario | Without RSA Sections |  | With RSA Sections |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Roughness | Description | Roughness | Description |
| Base Case | 10.9 | Poor | 9.6 | Poor |
| RN -1 | 2.2 | Excellent | 2.1 | Excellent |
| RN -2 | 2.8 | Very Good | 2.8 | Very Good |
| RN -3 | 3.6 | Good | 3.1 | Good |

The condition trends show that the requirements of achieving the three long-term condition targets are technically feasible, provided that the effects and timing of the predicted work for each scenario can be met. The financial investment requirements for each scenario are presented section 3.3.

Figure 3.1: Average Condition Trend for Each Scenario without RSA Road Sections

Figure 3.2: Average Condition Trend for Each Scenario with RSA Road Sections

### 3.3 Road Network Investment Needs

## Summary of Financial Costs

The financial requirements for maintaining the North-South Corridor road network and border posts over a 20 year period are given in Table 3.2 (without RSA roads) and Table 3.3 (with RSA roads). These tables show capital and recurrent estimates for the three scenarios RN-1, RN-2 and RN-3 and border post improvement scenario BP-3. Capital works include overlay, reconstruction, upgrading, partial widening, surface dressing, cape seal, and regravelling of unsealed roads. Recurrent works comprise routine activities such as crack sealing, edge-break repair, heavy grading, and spot regravelling amongst others.
Economic Benefits of an Efficient North-South Corridor
Table 3.2: Summary of Financial Costs (in Million US\$) by Scenario without the RSA Road Sections

| Road Network Improvement Scenarios | Road Sections Costs |  |  | Border Post Costs (BP-3 ${ }^{1}$ ) |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Capital | Recurrent | Sub-Total | Capital | Recurrent | Sub-Total |  |
| RN-1: Excellent Condition | 15,359 | 2,191 | 17,550 | 260 | 471 | 731 | 18,281 |
| RN-2: Very Good Condition | 9,227 | 2,235 | 11,461 | 260 | 471 | 731 | 12,192 |
| RN-3: Good Condition | 4,488 | 2,422 | 6,910 | 260 | 471 | 731 | 7,641 |

BP-3 = Border post improvement scenario BP-3 described in Table 2.14
Table 3.3: Summary of Financial Costs (in Million US\$) by Scenario with RSA Road Sections

| Road Network Improvement Scenarios | Road Sections Costs |  |  | Border Post Costs (BP-3 ${ }^{1}$ ) |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Capital | Recurrent | Sub-Total | Capital | Recurrent | Sub-Total |  |
| RN-1: Excellent Condition | 23,323 | 2,760 | 26,083 | 260 | 471 | 731 | 26,814 |
| RN-2: Very Good Condition | 13,774 | 2,842 | 16,616 | 260 | 471 | 731 | 17,347 |
| RN-3: Good Condition | 5,929 | 3,161 | 9,089 | 260 | 471 | 731 | 9,821 |

BP-3 $=$ Border post improvement scenario BP-3 described in Table 2.14

## Investments Required to Achieve Excellent Road Condition

The annual investment profile and the proportions of capital and recurrent expenditures necessary to keep the corridor roads (without RSA roads) in excellent condition are shown in Figures 3.3 and 3.4, respectively.

When corridor roads in the Republic of South Africa were excluded from the analysis, the financial investment required at the start of the analysis period was estimated to be US\$ 2.1 billion. This investment is required to clear maintenance backlogs and to improve the road condition to an excellent level. Thereafter, an annual average investment of approximately US\$ 853 million is required to maintain an excellent average road condition.

Figure 3.3: Annual Investment Profile for Scenario "RN-1, BP-3" without RSA Road Sections

Figure 3.4: Investment Cost Proportions for Scenario "RN-1, BP-3" without the RSA Road Sections

The annual investment profile and the proportions of capital and recurrent expenditures necessary to keep the corridor roads (with RSA roads) in excellent condition are shown in Figures 3.5 and 3.6, respectively. The initial annual investment required to improve the road condition to an excellent level was estimated to be US\$ 2.8 billion. Thereafter, an annual average investment of US\$ 1.1 billion is required to maintain an excellent average road condition.

Figure 3.5: Annual Investment Profile for Scenario "RN-1, BP-3" with the RSA Road Sections

Figure 3.6: Investment Cost Proportions for Scenario "RN-1, BP-3" with the RSA Road Sections

## Investments Required to Achieve Very Good Road Condition

The annual investment profile and the proportions of capital and recurrent expenditures necessary to keep the corridor roads (without RSA roads) in Very Good condition are shown in Figures 3.7 and 3.8, respectively. The financial investment requirement at the start of the analysis period was estimated to be US $\$ 1.8$ billion, see Figure 3.7. This investment is required to clear maintenance backlogs and to improve the road condition to Very Good. Thereafter, an annual average investment of about US\$ 547 million is required to maintain the corridor roads in very good condition.

Figure 3.7: Annual Investment Profile for Scenario "RN-2, BP-3" without the RSA Road Sections

Figure 3.8: Investment Cost Proportions for Scenario "RN-2, BP-3" without the RSA Road Sections

The annual financial investment profiles and the proportions of capital and recurrent expenditures needed to maintain the roads on the North-South Corridor (with RSA roads) in Very Good condition are shown in Figures 3.9 and 3.10. The financial investment required at the start of the analysis period was estimated to be US\$ 2.5 billion, see Figure 3.9. This investment is required to clear maintenance backlogs and to improve the road condition to Very Good.

Thereafter, an annual average investment of about US\$ 660 million is required to maintain the road sections in very good condition.

Figure 3.9: Annual Investment Profile for Scenario "RN-2, BP-3" with the RSA Road Sections

Figure 3.10: Investment Cost Proportions for Scenario "RN-2, BP-3" with the RSA Road Sections

## Investments Required to Achieve Good Road Condition

The annual investment profile and the proportions of capital and recurrent expenditures necessary to keep the corridor roads (without RSA roads) in good condition are shown in Figures 3.11 and 3.12, respectively. The financial investment needed to clear maintenance backlogs and improve the road condition to Good was estimated to be US\$ 1.2 billion. In order to maintain the corridor roads (without RSA roads) in good condition in the long-term, an average of US\$ 328 million per year is required.

Figure 3.11: Annual Investment Profile for Scenario "RN-3, BP-3" without the RSA Road Sections

Figure 3.12: Investment Cost Proportions for Scenario "RN-3, BP-3" without the RSA Road Sections

The annual financial investment profile and the proportions of capital and recurrent expenditures needed to improve and maintain the North-South corridor roads (with RSA roads) in Good condition are shown in Figures 3.13 and 3.14. When the road sections in the Republic of South Africa were included in the analysis, the financial requirement at the start of the analysis period to clear maintenance backlogs and achieve Good road condition was estimated to be US\$ 1.9 billion, see Figure 3.13. Thereafter, an annual average investment of US\$ 360 million is required to maintain the corridor roads in good condition over the analysis period.

Figure 3.13: Annual Investment Profile for Scenario "RN-3, BP-3" with the RSA Road Sections

Figure 3.14: Investment Cost Proportions for Scenario "RN-3, BP-3" with the RSA Road Sections

## Comparison of Investment Needs for Scenarios RN-1, RN-2, and RN-3

With the exclusion of road sections in the Republic of South Africa from the analysis, the total capital and recurrent expenditures required over 20 years to improve and maintain the corridor roads in Excellent condition (RN-1) is US\$ 17.6 billion. This exceeds the total financial investment that would be needed to improve and maintain the corridor roads to Very Good (RN-2) and Good (RN-3) condition by about $53 \%$ and $154 \%$, respectively. The average annual road network maintenance expenditure per km of road length for each scenario is approximately 40,000 US\$ for Scenario RN-3, 66,300 US\$ for Scenario RN-2, and 101,500 US\$ for Scenario RN-1.

When road sections within the Republic of South Africa are included in the analysis, the total financial requirement to improve and maintain the corridor roads in excellent condition over 20 years increases to US\$ 26.1 billion. This is more than the estimated total investment required to keep the corridor roads (with RSA roads) in Very Good and Good condition by $57 \%$ and $187 \%$, respectively. The average annual road network maintenance expenditure per lane km of road length for each scenario is approximately 43,100 US\$ for Scenario RN-3 (Good Condition), 78,800 US\$ for Scenario RN-2 (Very Good Condition), and 123,700 US\$ for Scenario RN-1 (Excellent Condition).

A total capital and recurrent investment of US\$ 731 million, see Tables 3.2 and 3.3 , over 20 years is required to reduce the current levels of delays at border posts by half.

### 3.4 Economic Benefits

The Net Present Values (NPVs) over a 20-year analysis period for different investment scenarios are summarised in Table 3.4 (without RSA roads) and Table 3.5 (with RSA roads). The results suggest that investment scenario "RN-3, BP-3" provides the highest amount of benefits which is equivalent to about US\$ 30.0 billion (with RSA roads) and US\$ 14.7 billion (without RSA roads). The road condition trends over the 20 year analysis period, discussed in Section 3.2, show that this combination would result in good road condition in the long term provided that the predicted maintenance and improvement investments are
adhered to sufficiently and timely. A work programme by sections for this investment scenario is summarised in Table D. 1 in Appendix D.

A summary of key economic indicators including annualised financial costs and economic benefits are given in Table 3.6 (without RSA roads) and Table 3.7 (with RSA roads).
Economic Benefits of an Efficient North-South Corridor

### 3.5 Cumulative Net Economic Benefits

An important aim of the study was to investigate the timing of positive cumulative net economic benefit to society for selected combinations of road condition and border post improvement scenarios. The results for investment scenario "RN-2, BP-3" are presented in Figure 3.15 (without RSA roads) and Figure 3.16 (with RSA roads) respectively. The results for investment scenario "RN-3, BP-3" are presented in Figure 3.17 (without RSA roads) and Figure 3.18 (with RSA roads), respectively.

## Investment Scenario "RN-2, BP-3"

Figure 3.15 shows that a positive cumulative net economic benefit is expected from year 7, while Figure 3.16 indicates that a positive cumulative net economic benefit is expected from year 9 .

Figure 3.15: Cumulative NPV for Investment Scenario "RN-2, BP-3" without the RSA Road Sections

Figure 3.16: Cumulative NPV for Investment Scenario "RN-2, BP-3" with the RSA Road Sections

## Investment Scenario "RN-3, BP-3"

Figure 3.17 shows that when road sections in the Republic of South Africa are excluded, a positive cumulative net economic benefit is expected from year 5, and when roads in the Republic of South Africa are included then a positive cumulative net economic benefit is expected from year 7 as shown in Figure 3.18. It is important to note that this does not imply that the inclusion of road sections in the Republic of South Africa makes the investment case economically or financially less attractive. On the contrary, Table 3.7 shows that the benefit/cost ratios are higher when road sections in the Republic of South Africa are included. Also, the annual investment profiles given in Figure 3.12 (without RSA roads) and Figure 3.13 (with RSA roads) provide useful explanation. Figure 3.13 shows that the financial investment requirements in the initial analysis period are much higher than in Figure 3.12.

In general, the year in which positive cumulative benefits may be realised could be affected by uncertainties in determining the values of the most sensitive input data used in the study as discussed in section 3.7.

Figure 3.17: Cumulative NPV for Investment Scenario "RN-3, BP-3" without the RSA Road Sections

Figure 3.18: Cumulative NPV for Investment Scenario "RN-3, BP-3" with the RSA Road Sections

### 3.6 Comparison of Net Present Values for Selected Routes

A comparison of the total net benefits over 20-year analysis period for 7 routes within the North-South Corridor was conducted for the without and with the RSA roads analysis for the combination of Scenario RN-3 and Scenario BP-3.

## Routes NPV (without RSA roads)

All seven routes have positive net benefits over a 20 -year analysis period. Route 7 has the lowest NPV, while routes 1, 2, 4 and 5 are economically very attractive, see Table 3.8.

Table 3.8: Total Net Present Value for Key Routes (without the RSA Road Sections)

| Route <br> Number | Description | Total NPV (Million <br> US $\$$ ) |
| :---: | :--- | :---: |
| 1 | Kolwezi - Kasumbelesa -Chingola (including <br> traffic from Solwezi) - Kapiri Mposhi - Lusaka - <br> Chirundu - Harare - Beit Bridge | 4,320 |
| 2 | Kolwezi - Kasumbelesa -Chingola (including <br> traffic from Solwezi) - Kapiri Mposhi - Lusaka - <br> Kafue - Livingstone - Bulawayo - Beit Bridge | 4,300 |
| 3 | Kolwezi - Kasumbelesa -Chingola (including <br> traffic from Solwezi) - Kapiri Mposhi - Lusaka - <br> Kafue - Livingstone - Kazangula - Nata - Francis <br> Town - Gaborone | 3,144 |
| 4 | Kolwezi - Kasumbelesa - Chingola (Including <br> trafic from Solwezi) - Kapiri Mposhi - Nakonde - <br> Mbeya - Iringa - Dar es Salaam | 4,177 |
| 5 | Dar-es-Salaam - Mbeya - Lilongwe | 4,200 |
| 6 | Lilongwe - Mwanza - Nyampanda - Harare - Beit <br> Bridge | 2,077 |
| 7 | Lusaka - BPMchinji - Liliongwe- Blantyre | 1,096 |

## Routes NPV (with RSA roads)

All seven routes have positive NPVs over a 20-year analysis period. Route 7 has the lowest NPV while routes 1,2,3 and 6 are even more attractive economically with the inclusion of road sections in the Republic of South Africa which carry high traffic volumes, see Table 3.9.

Table 3.9: Total Net Present Value for Key Routes with the RSA Road Sections

| Route <br> Number | Description | Total NPV <br> (Million US\$) |
| :---: | :--- | :---: |
| 1 | Kolwezi - Kasumbelesa -Chingola (including traffic <br> from Solwezi) - Kapiri Mposhi - Lusaka - Chirundu - <br> Harare - Beit Bridge - Johannesburg - Durban | 18,047 |
| 2 | Kolwezi - Kasumbelesa -Chingola (including traffic <br> from Solwezi) - Kapiri Mposhi - Lusaka - Kafue - <br> Livingstone - Bulawayo - Beit Bridge - Johannesburg | 18,027 |
| 3 | - Durban <br> from Sozi - Kasumbelesa -Chingola (including traffic <br> Livingstone - Kazangula - Nata - Francis Town - <br> Gaborone - Johannesburg - Durban | 12,355 |
| 4 | Kolwezi - Kasumbelesa - Chingola (Including traffic <br> from Solwezi) - Kapiri Mposhi - Nakonde - Mbeya - <br> lringa - Dar es Salaam | 4,177 |
| 5 | Dar-es-Salaam - Mbeya - Lilongwe |  |
| 6 | Lilongwe - Mwanza - Nyampanda - Harare - Beit <br> Bridge - Johannesburg - Durban | 15,735 |
| 7 | Lusaka - BPMchinji - Liliongwe- Blantyre | 4,200 |
| 2 | 1,096 |  |

### 3.7 Sensitivity of Key Input Data

It is important to recognise the medium and low levels of confidence in some of the data used in this study. A sensitivity analysis was therefore undertaken to determine the effects of variations in the values of key input data on NPV and the timing of positive cumulative net economic benefits. The input parameters tested are initial AADT, traffic growth rate, construction costs and travel time value. The base values used in the study were varied from $-50 \%$ to $+50 \%$. The results are summarised for analysis without and with the RSA roads for Investment Scenario "RN-3, BP-3".

## Sensitivity analysis without the RSA road sections

A summary of the sensitivity analysis on the timing of positive cumulative net economic benefit is given in Table 3.10 for without RSA road sections. The results suggest, for example, that if values of initial AADT for every road section were lower by $50 \%$, then a positive cumulative net economic benefit would be
realised starting from year 7 instead of year 5. Construction cost is the most sensitive parameter with respect to the timing of positive cumulative net economic benefits, while traffic growth and travel time value are less sensitive parameters.

Table 3.10: Sensitivity of key Parameters on the Timing of Positive Cumulative Net Economic Benefits (without the RSA roads)

| Parameter | Initial Year of Positive Cumulative Net Benefits |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{- 5 0 \%}$ <br> change | $\mathbf{- 2 5 \%}$ <br> change | $\mathbf{0 \%}$ <br> change | $\mathbf{+ 2 5 \%}$ <br> change | $\mathbf{+ 5 0 \%}$ <br> change |
|  | 7 | 5 | 5 | 4 | 4 |
| Traffic Growth <br> Rate | 5 | 5 | 5 | 4 | 4 |
| Construction Cost | 3 | 4 | 5 | 5 | 6 |
| Travel Time <br> Value | 5 | 5 | 5 | 5 | 5 |

1. AADT = Average Annual Daily Traffic

Table 3.11 presents the results of sensitivity analysis of the selected parameters on NPV. Figure 3.19 is a "spider diagram" that illustrates the degree of sensitivity of each parameter tested on NPV. With respect to NPV, initial AADT is clearly the most sensitive parameter followed by traffic growth rate. Travel time value and construction costs are less sensitive parameters.

Table 3.11: Sensitivity of Key Parameters on Total NPV (without the RSA roads)

| Parameter | Total NPV Over 20 Years in Million US\$ |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{- 5 0 \%}$ <br> change | $\mathbf{- 2 5 \%}$ <br> change | 0\% <br> change | $\mathbf{+ 2 5 \%}$ <br> change | $\mathbf{+ 5 0 \%}$ <br> change |
| Initial AADT | 5,325 | 9,690 | 13,875 | 20,101 | 25,631 |
| Traffic Growth <br> Rate | 10,585 | 12,465 | 13,875 | 17,353 | 20,520 |
| Construction Cost | 15,603 | 15,161 | 13,875 | 14,279 | 13,838 |
| Travel Time <br> Value | 14,720 | 14,720 | 13,875 | 14,720 | 14,720 |

Figure 3.19: Sensitivity of Key Parameters on Total NPV (without the RSA roads)

Further sensitivity analysis was carried out to identify the smallest traffic growth rate such that the NPV still becomes positive. The reason for this is to allow for traffic either diverting onto the railways or to other routes. The results given in Table 3.12 shows that even at zero percent traffic growth rate the NPV over 20year analysis period is positive US\$ 7.647 billion for investment scenario "RN-3, BP-3".

Table 3.12: Effect of Traffic Growth Rate on total NPV (without the RSA roads)

| Traffic Growth Rate <br> (\%) | Year when Cumulative Net <br> Economic Benefit becomes <br> Positive | Total NPV (Million US\$) |
| :---: | :---: | :---: |
| 0 | 5 | 7,647 |
| 1 | 5 | 8,710 |
| 2.5 | 5 | 10,585 |
| 5 | 5 | 14,720 |

## Sensitivity analysis with the RSA road sections

Table 3.13 gives a summary of the results of sensitivity analysis on the timing of positive cumulative net economic benefits. The results suggest, for example, that
if construction costs were higher by $50 \%$, then a positive cumulative net benefit to society would start to accrue from year 9 instead of year 8 . Again, construction cost and initial AADT are the most sensitive parameters with respect to the timing of net economic benefits, while traffic growth rate and travel time value are less sensitive parameters.

Table 3.13: Sensitivity of Key Parameters on Positive Cumulative Net Economic Benefits (with the RSA roads)

| Parameter | Initial Year of Positive Cumulative Net Benefits |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{- 5 0 \%}$ <br> change | $\mathbf{- 2 5 \%}$ <br> change | $\mathbf{0 \%}$ <br> change | $\mathbf{+ 2 5 \%}$ <br> change | $\mathbf{+ 5 0 \%}$ <br> change |
| Initial AADT | 8 | 7 | 8 | 8 | 7 |
| Traffic Growth <br> Rate | 7 | 7 | 8 | 8 | 8 |
| Construction Cost | 6 | 7 | 8 | 8 | 9 |
| Travel Time <br> Value | 8 | 8 | 8 | 8 | 8 |

Table 3.14 and Figure 3.20 present the results of sensitivity analysis carried out with respect to changes in NPV due to variation in values of the selected parameters. Again, initial AADT is clearly the most sensitive parameter followed by traffic growth rate. Travel time value and construction costs are less sensitive parameters.

Table 3.14: Sensitivity of Key Parameters on Total NPV (with the RSA roads)

| Parameter | Total NPV Over 20 Years in Million US\$ |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{- 5 0 \%}$ <br> change | $\mathbf{- 2 5 \%}$ <br> change | 0\% <br> change | $\mathbf{+ 2 5 \%}$ <br> change | $\mathbf{+ 5 0 \%}$ <br> change |
| Initial AADT | 12,533 | 20,889 | 29,191 | 40,922 | 57,556 |
| Traffic Growth <br> Rate | 20,829 | 24,752 | 29,191 | 38,170 | 49,797 |
| Construction Cost | 31,282 | 30,656 | 29,191 | 29,402 | 28,775 |
| Travel Time <br> Value | 30,029 | 30,029 | 29,191 | 30,029 | 30,029 |

Figure 3.20: Sensitivity of Key Parameters on Total NPV (with the RSA roads)

Further sensitivity analysis was carried out to identify the smallest traffic growth rate such that the NPV still becomes positive. The reason for this is to allow for traffic either diverting onto the railways or to other routes. The results given in Table 3.15 shows that even at zero percent traffic growth rate the NPV over 20year analysis period is positive US\$ 15.135 billion for investment scenario "RN-3, BP-3".

Table 3.15: Effect of Traffic Growth Rate on total NPV (with the RSA roads)

| Traffic Growth <br> Rate (\%) | Year when Cumulative Net <br> Economic Benefit becomes <br> Positive | Total NPV <br> (US\$ Million) |
| :---: | :---: | :---: |
| 0 | 7 | 15,135 |
| 1 | 7 | 17,476 |
| 2.5 | 7 | 20,829 |
| 5 | 8 | 30,029 |

## 4 CONCLUSION AND THE WAY FORWARD

This study has demonstrated that there is an attractive rate of return to be realised from investment in the North-South Corridor. The study was based on an appropriate methodology and a more advanced use of the highway development and management (HDM-4) tool.

Two sets of analysis were carried out; one involved all the road sections on the North-South Corridor and the other excluded road sections in the Republic of South Africa. Different investment scenarios were analysed separately and the following are the main conclusions from the study:

- The most viable investment scenario in economic terms is for Road Agencies to maintain all the roads on the North-South Corridor in Good condition, which is denoted Scenario "RN-3, BP-3". Technically the longterm average road condition, over the 20 -year analysis period, would be 3.1 IRI. The total financial investment required for road network improvement is US\$ 9.1 billion of which US\$ 5.9 billion is capital investment and US\$ 3.2 billion is recurrent costs. The total financial requirement for border post improvement is US\$ 0.73 billion of which US\$ 0.26 billion is capital investment and US $\$ 0.47$ billion is recurrent costs. The annualised financial requirement to improve the road network is approximately US\$ 43,100 per km . The economic return on this investment (i.e. the NPV) would be US\$ 29.2 billion. The benefit/capital cost ratio associated with this investment is 6.5.
- When road sections from the Republic of South Africa are excluded from the analysis, investment scenario "RN-3, BP-3" remains the most economically attractive. The long-term average road condition, over the 20-year analysis period, would be 3.6 IRI . The total financial investment required for road network improvement is US\$ 6.9 billion of which US\$ 4.5 billion is capital investment and US\$ 2.4 billion is recurrent costs. The total financial requirement for border post improvement is US\$ 0.73 billion of which US\$ 0.26 billion is capital investment and US $\$ 0.47$ billion is recurrent costs. The annualised financial requirement to improve the road network is approximately US\$ 40,000 per km . The economic return on this investment
(i.e. the NPV) would be US\$ 13.9 billion. The benefit/capital cost ratio associated with this investment is 3.1 .
- The results of sensitivity analysis have indicated that even at zero percent rate of traffic growth (to crudely assess the effect of traffic diversion to other transport modes and routes/corridors) the NPV of investment scenario "RN3 , BP-3" is still positive US\$ 15.1 billion for all road sections, and positive US\$ 7.6 billion when road sections in the Republic of South Africa are excluded.
- The results show that in the initial years of the 20 -year analysis period, higher amounts of investment expenditures are required to eliminate maintenance backlogs and raise the road standard to an appropriate level for the North-South Corridor.
- The approximate timing when the cumulative net economic benefit of investments will become positive was determined to be Year 9 (with RSA roads included) and Year 7 (without RSA roads) for investment scenario RN2 (i.e. the Road Agencies shall maintain the roads on the North-South Corridor to Very Good condition); and Year 7 (with RSA roads) and Year 5 (without RSA roads) for Scenario RN-3. It is important to note that this does not imply that the inclusion of road sections in RSA makes the investment cases economically less attractive. On the contrary, analysis results have shown that the benefit/ capital cost ratios are higher when road sections in RSA are included. This perhaps stresses the need for carrying out a financial analysis of the corridor roads, the results of which would indicate to the private sector when they could get seriously involved in investing in the North-South Corridor.
- The NPV of selected key routes within the North-South corridor have also been determined to show the degree of economic attractiveness of each route. A full road works programme for 20 years has also been produced showing when each section is to receive an intervention with costs.

## The Way Forward

It should be noted that the reliability of the results of any studies using prediction models such as HDM-4 is dependent upon two primary considerations:

- How well the data provided to the model represent the reality of the current conditions and influencing factors, in the terms understood by the model; and,
- How well the predictions of the model fit the real behaviour and the interactions between various factors for the conditions prevailing in the countries and regions to which it is applied.

Although the study team made great effort to obtain reliable input data and calibrate the models, available project resources limited this. Nevertheless, the rigorous sensitivity analysis conducted has confirmed the robustness of the results obtained. Largely, default HDM-4 model parameters and data obtained from desk studies were used. Confidence in using the results obtained from this study could be increased through additional studies to:

1. Calibrate HDM-4 models to conditions within the North-South Corridor to Level 2 Calibration;
2. Validate the data held by the various road agencies that manage road sections within the corridor in order to determine their appropriateness for use in future studies of the North-South Corridor;
3. Investigate the impact of overloading of goods vehicles on road deterioration; and
4. Carry out a financial analysis of investments in the North-South Corridor to assess how the private sector could get involved, for example, through Public-Private-Partnership (PPP) or other appropriate investment models.

## Appendix B: Vehicle Fleet Data

| Data Type | Unit | Description | Data Values |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Cars | Light Vehicles | Medium Vehicles | Heavy Vehicles | Bus |
| Number of Axles | No | Number of axles per vehicle | 2 | 2 | 2 | 4 | 2 |
| Number of Wheels | No | Number of wheels per vehicle | 4 | 4 | 6 | 14 | 6 |
| Annual Utilisation in km | km | Average number of kilometres driven per year | 22,500 | 45,000 | 80,000 | 100,000 | 75,000 |
| Working hours | hr | Number of hours per year expended on essential tasks of complete round trips | 450 | 1,200 | 1,500 | 1,800 | 1,200 |
| Average Life | Year | Average vehicle service life | 9 | 10 | 8 | 8 | 10 |
| Equivalent Standard Axle Load Factor | - | Number of equivalent standard axles per vehicle | - | 1.00 | 4.30 | 4.60 | 2.40 |
| Operating Weight | Ton | Average operating vehicle of the vehicle | 2.15 | 4.00 | 12.30 | 40.00 | 12.60 |
| Cost of New Vehicle | US\$ | Average purchase costs (economic costs) of new vehicle of this type. | 18,591 | 38,234 | 59,919 | 96,639 | 76,408 |
| Fuel Cost | US\$ | Average costs of fuel per litre. | 0.55 | 0.59 | 0.59 | 0.59 | 0.59 |
| Passenger Working Time Value | US\$ | The average costs value of passenger working time (per hour) | 0.07 | 0.07 | 0.07 | 0.07 | 0.07 |
| Passenger Non-Working Time Value | US\$ | The average cost value of passenger nonworking time (per hour) | - | - | - | - | - |
| Cargo delay costs | $\begin{gathered} \text { US\$ } \\ \text { /hr } \end{gathered}$ | The average costs of cargo delay per hour | - | 0.02 | 0.02 | 0.02 | - |

Economic Benefits of an Efficient North-South Corridor
Notes to Table C. 1
Summary of Data Sources:

1. Botswana - (Roads Department, Botswana)

- Traffic levels were considered higher at the DRC-Zambia border than inland towards Kolwezi to reflect existing economic activities
tracao Nacional de Estradas (ANE), Project Report (2007): Consultancy Services for a Heavy Vehicle Overloading Control Study
SA - (The South African National Roads Agency - Major Project Reports)

7. Zambia - (Roads Development Agency, Zambia)
Generally the national level of traffic in Zimbabwe was considered similar to that of Zambia
AADT were estimated based on international traffic through international borders with Zimbabwe
8. Estimated AADT were adjusted to reflect local traffic especially for the sections through major economic locations
